Welcome

Welcome to CoreDX DDS, a high-performance implementation of the OMG Data Distribution Service (DDS) standard. The CoreDX DDS Publish-Subscribe messaging infrastructure provides high-throughput, low-latency data communications.

This Quick Start will guide you through the basic installation of CoreDX DDS, including installation and compiling and running an example Java application. You will learn how easy it is to integrate CoreDX DDS into an application. This Quick Start Guide is tailored for Java applications, and the examples differ slightly for other languages.

Installation

First things first: get CoreDX DDS onto your development system! Here's what you need to do:

1. Once you have obtained CoreDX DDS from Twin Oaks Computing (or from the Eval CD), unpack the appropriate distribution for your machine somewhere on your system. We'll refer to this directory throughout this guide as COREDX_HOME. For example, on a UNIX system this command will extract the distribution into the current directory:

```
gunzip -c coredx-3.0-Linux_2.6_i686-Release.tar.gz | tar xvf -
```

CoreDX DDS is available for multiple platform architectures, and multiple platform architectures of CoreDX DDS can be installed in the same top level (COREDX_TOP) directory. The directory structure under COREDX_TOP will look like:

2. If you are using an evaluation copy of CoreDX DDS, follow the instructions you received when you downloaded the software to obtain an evaluation license. Otherwise, use the purchased license provided by Twin Oaks Computing. Once you have the license, put this file somewhere on your system. We'll refer to the full path name to this file throughout this guide as LICENSE_FILE.

Building an Application

Next, integrate CoreDX DDS into an application! We've provided a sample data type and application with the distribution (located in COREDX_TOP/examples). You can use these examples or create your own while going through the following steps.

1. Create the Data Definition Language (DDL) file for the data type(s) you will use for communications. The CoreDX DDS DDL syntax is very similar to the OMG IDL syntax for describing data types. Here is the "hello world" example provided with the distribution:

```
hello.ddl
struct StringMsg
{
    string msg;
};
```

2. Tell the CoreDX DDS DDL compiler where your evaluation license is located. You can copy the license file into the directory where you will run the compiler; or set the following environment variable, using the full path to your license file. (This assumes a *bash* style shell):

```
% export TWINOAKS_LICENSE_FILE=LICENSE_FILE
```

3. Compile the DDL to generate the type specific code using the CoreDX DDS DDL compiler. The DDL compiler is a *host* tool, and is located in the host subdirectory. Actually, there may be more than one DDL compiler, if you have multiple platform versions of CoreDX DDS installed. In this case, choose the appropriate compiler for your architecture. Assuming we are using a Linux distribution and the name of the DDL file is hello.ddl (we use the one in the hello_c example directory):

```
% COREDX_TOP/host/bin/Linux_26_x86_gcc43_coredx_ddl -f
../hello_c/hello.ddl -l java
```

The compilation will generate the following files (file names are based on the DDL type name):

- StringMsg.java
 - StringMsgTypeSupport.java
 - StringMsgDataReader.java
 - StringMsgDataWriter.java
4. Create code to publish data of this data type. Our sample Hello World publisher is located in COREDX_HOME/examples/hello_java/HelloPub.java.
 5. Create code to subscribe to data of this data type. Our sample Hello World subscriber is located in COREDX_HOME/examples/hello_java/HelloSub.java.
 6. Compile your application(s). Our Hello World example creates two applications, one for the publisher and one for the subscriber. This is not necessary, and is completely dependent on your application architecture. Your application will require the objects from the generated type support code above, as well as your publisher and/or subscriber code.

CoreDX DDS will require the following paths and libraries when compiling your application:

```
Class Path: -cp classes -cp \  
            ${COREDX_TOP}/target/java/coredx_dds.jar
```

We've provided a compile.sh (UNIX) and compile.bat (Windows) for compiling our example. You can use these as a reference for compiling your application. Our scripts require three environment variables:

1. COREDX_TOP
2. COREDX_HOST
3. COREDX_TARGET

The COREDX_TOP is a path name to the location of your CoreDX DDS distribution(s). COREDX_HOST and COREDX_TARGET are the platform architectures you are compiling on and compiling for (these can be the same). These values can be set manually, or determined by running the script: COREDX_TOP/scripts/cdxenv.sh or cdxenv.bat.

Our scripts will run the DDL compiler to generate the type specific code as well as compile the applications. To compile the Hello World sample application using our scripts you will need the Java DJK (specifically, javac) in your path. Then, simply run 'compile.sh' for UNIX or 'compile.bat' for Windows in the appropriate directory.

This will compile several class files, including the HelloPub and HelloSub classes.

Running a Test Application

You've written some code, generated some code, and compiled it all. Now for seeing it all work! You will need at least one environment variable to run:

TWINOAKS_LICENSE_FILE = The full path to your evaluation license

You will also need the same COREDX environment variables needed for the compile above:

1. COREDX_TOP
2. COREDX_HOST
3. COREDX_TARGET

Run your application(s). We provide scripts to run the example hello_pub and hello_sub applications. For UNIX:

```
run_sub.sh  
run_pub.sh
```

For Windows:

```
run_sub.bat  
run_pub.bat
```

Congratulations! You have now built and run two applications that are communicating using CoreDX DDS.

Figure 1 shows a picture of what you have built:

You can run multiple Publishers and multiple Subscribers to immediately see the dynamic nature of the DDS network infrastructure. These Publishers and Subscribers can be run on the same host or on multiple hosts across a network.

A few notes about the Transport

The CoreDX DDS transport conforms to the Real-Time Publish-Subscribe (RTPS) Wire Protocol. This transport does not use a stand-alone transport daemon, and does not require configuration of any operating system services.

Configuring the Transport

The CoreDX DDS RTPS transport can be configured using the following environment variables.

Environment Variable	Values	Description
CORED_X_IP_ADDR	Valid, Local IP address	As part of discovery, each DDS DomainParticipant advertises local IP addresses that peers can use to communicate with it. If your machine has multiple network interfaces, CoreDX DDS will by default advertise (and use) all interfaces for DDS communications. This may generate unnecessary network traffic on some of those networks. This environment variable will limit DDS traffic to just one interface – the interfaces specified by the IP address.
CORED_X_USE_MULTICAST	“YES”, “NO”	By default, CoreDX DDS RTPS will use multicast for data communications between DDS participants where it can. To specify unicast data communications, set this environment variable to “NO”. This only effects data communications, discovery will still use multicast.
CORED_X_MULTICAST_TTL	integer > 0	This is the time to live (TTL) set on all the multicast packets (including those used for discovery). By default, CoreDX DDS uses the operating system configured TTL (generally “1”). Increasing this allows the multicast packets to survive going through network routers.
CORED_X_MIN_TX_BUFFER_SIZE	400 - 65400	(in bytes) The CoreDX DDS RTPS transport will combine multiple data packets to send over the network to reduce network overhead and improve performance. By default, the transmit buffer size is <i>dynamic</i> . For cases where IP fragmentation and reassembly is not implemented well in either the network hardware or operating system, it is necessary to fix the transmit buffer to a smaller size. This environment variable controls the minimum size of the

Environment Variable	Values	Description
		transmit buffer on every DataWriter within a DomainParticipant (including Built-in DataWriters).
CORED_X_MAX_TX_BUFFER_SIZE	401-65400	(in bytes) The CoreDX DDS RTPS transport will combine multiple data packets to send over the network to reduce network overhead and improve performance. By default, the transmit buffer size is <i>dynamic</i> . For cases where IP fragmentation and reassembly is not implemented well in either the network hardware or operating system, it is necessary to fix the transmit buffer to a smaller size. This environment variable controls the maximum size of the transmit buffer on every DataWriter within a DomainParticipant (including Built-in DataWriters).
CORED_X_MAX_RX_BUFFER_SIZE	401 - 65536	This environment variable determines the receive buffer size for every DomainParticipant. By default, this buffer is dynamically sized based on the data packets received by the DomainParticipant.

A few notes about License Files

CoreDX DDS uses development and run-time licenses. A development license is required for using the CoreDX DDS DDL compiler (coredx_ddl). A run-time license is required for making CoreDX DDS library function calls. Both licenses are contained in a license file provided by Twin Oaks Computing. Here is an example license file containing evaluation licenses for both development and run-time:

```
coredx.lic
#=====
# CoreDX DDS Evaluation License file
#
# Created: <today> by Twin Oaks Computing, Inc.
# Contains: 30 day evaluation development licenses, evaluation run-time licenses
#
#=====

LICENSE PRODUCT=coredx_ddl EXP=31-Aug-2008 BUILD=Evaluation

da8fa73cc69d3572738259025c212815aef2f94111580f51583e437
```

This evaluation license file contains two LICENSE lines. The first is the development license for the CoreDX DDS DDL compiler. The second is the run-time license for the CoreDX DDS library. All evaluation licenses have expiration dates. In the example file above, the licenses expire on Aug 31, 2008.

The CoreDX DDS software requires a license environment variable be set: TWINOAKS_LICENSE_FILE. This environment variable can contain either:

- The fully qualified name of the license file
- The entire LICENSE line from the license file contained in angle brackets: < >

For development (to run the coredx_ddl compiler), you must set the TWINOAKS_LICENSE_FILE environment variable to the license file.

For run-time, you can use either method listed above. If you have access to the license file from your run-time environment, this is the simplest way to use the license. Simply set a TWINOAKS_LICENSE_FILE environment variable to the license file.

If you do not have access to the license file at run-time, you can set the TWINOAKS_LICENSE_FILE environment variable to the LICENSE line. For the run-time license in the above example license file, set your TWINOAKS_LICENSE_FILE like:

```
% export TWINOAKS_LICENSE_FILE="<LICENSE PRODUCT=coredx_c BUILD=Evaluation  
EXP=31-Aug-2008 CUSTOMER=Company_X SIG=30b3c5d6f941c5ff5e46384eb1b74bd1

0f51583e437>"
```

A Few Notes About DDS Keys

DDS provides a facility for user defined data types to identify one or more fields as a “key”. By specifying a key, the published data will be categorized into instances. An instance refers to a collection of samples, where each sample has an identical key value. For example, consider a data type that has a field ‘x’ identified as the key and the type of ‘x’ is a long integer. All samples with x=5, belong to the same instance. A DataWriter can publish several samples with x=5 and they all refer to the same instance. The DDS middleware can be configured, via the History QoS, to keep all samples of an instance, or only a certain number of samples.

You specify the key for your data type by inserting some additional information into the DDL file. This provides an indication to the DDL compiler that it should generate additional code to correctly handle the key information.

For example:

```
Hello_key.ddl

#ifdef DDS_IDL
#define DDS_KEY __dds_key
#else
#define DDS_KEY
#endif

struct StringMsg
{
    DDS_KEY long    id;
                string msg;
};
```

This example adds a key called ‘id’. The #ifdef block at the beginning simply removes the “DDS_KEY” symbol if the file is not being processed by the CoreDX DDS DDL compiler. This ensures that **ddl** files maintain compatibility with standard IDL syntax.

Several fields can be marked with the DDS_KEY modifier. In this case, all ‘key’ fields are used together as the key for the data type.

A few notes about the DDL Compiler (coredx_ddl)

The coredx_ddl compiler handles a few command line arguments. The following briefly describes the command line options and arguments. (The '-h' argument can be used to list all the command line arguments accepted by the coredx_ddl compiler.)

-f <filename>	Specifies the DDL file to compile. This is a required argument.
-l <language>	Specifies the language to generate: 'c' for C code, 'cpp' for C++ code. The default if not specified is 'c'.
-d <output directory>	Specifies the output directory where the generated source code should be placed. By default, the files are placed in the current working directory.
-D <preprocessor symbol>	This option is used to specify preprocessor defines.
-I <include path>	This option provides a path that will be searched to satisfy '#include' directives found in the DDL file(s).

About Twin Oaks Computing

With corporate headquarters located in Castle Rock, Colorado, USA, Twin Oaks Computing is a company dedicated to developing and delivering quality software solutions. We leverage our technical experience and abilities to provide innovative and useful services in the domain of data communications. Founded in 2005, Twin Oaks Computing, Inc delivered the first version of CoreDX DDS in 2008. The next two years saw deliveries to over 100 customers around the world. We continue to provide world class support to these customers while ever expanding.
